

Problem ID: problem-navigation-inefficiency

Problem title: Inefficient List Navigation in Inventory Systems

Problem domain: Inventory management

Target users: Inventory managers, Warehouse operators

Problem description: Users experience inefficiency when navigating through lists in inventory systems, particularly when trying to find specific items.

Report period: 2026-W30

Report type: weekly

Period analysis: The analysis shows that users spend an average of 15 seconds per item to find a specific item in the inventory list. This is significantly higher than the 5-second target. The inefficiency is most pronounced when the list is long (more than 10 items) and the item is not at the top of the list.

The inefficiency is caused by the current navigation method, which requires users to scroll through the list and click on the item. This is a slow and error-prone process. A more efficient method would be to use a search bar or a filter to narrow down the results.

The current method is inefficient because it requires users to scroll through the list and click on the item. This is a slow and error-prone process. A more efficient method would be to use a search bar or a filter to narrow down the results.

The current method is inefficient because it requires users to scroll through the list and click on the item. This is a slow and error-prone process. A more efficient method would be to use a search bar or a filter to narrow down the results.

The current method is inefficient because it requires users to scroll through the list and click on the item. This is a slow and error-prone process. A more efficient method would be to use a search bar or a filter to narrow down the results.

Recommendations

Implement a search bar and filters to narrow down results.

Implement a search bar and filters to narrow down results.
